

CloudTrail Logging Internals

A methodology for investigating AWS security incidents

Eliav Levy, Lead Security Researcher @ Hunters

aws sts get-caller-identity

Agenda

- Investigating an incident
 - What questions to ask
 - How to ask those questions
 - CloudTrail internals
- Fun examples of CloudTrail-complexity

Let's start with an incident

Discovery:IAMUser/AnomalousBehavior  

Finding ID: [bbdbdd944d7fa220a8f10fe73276617](#) [Feedback](#)

High User AssumedRole : admin is anomalously invoking APIs commonly used in Discovery tactics. [Info](#)

[Investigate with Detective](#)

Disclaimer

There are simpler things than this methodology that can give 80% (Pareto) results.

We're going for 99%.

Before we continue...

Prerequisites:

- CloudTrail logging enabled
- Logs accessible and queryable (Athena / DB / etc.)
- Best-practice CloudTrail configuration

Answering “who did it?”

We know that:

`arn:aws:sts::222222222222:assumed-role/admin/itadmin`
was used.

But - which person or system was using this identity?

This is non-trivial to answer accurately.

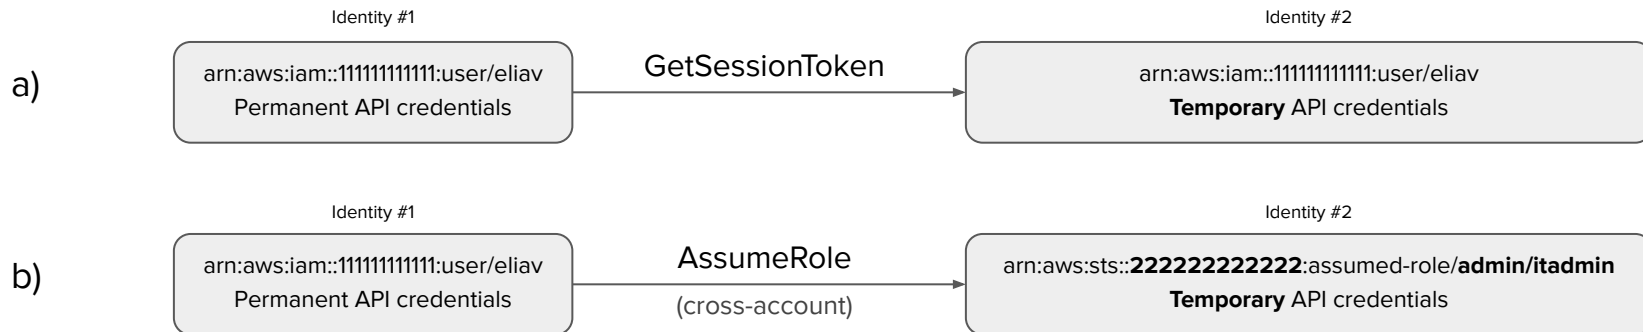

AWS Identity Chains

There are several API calls that pivot between identities.

Some pivot between AWS accounts, and/or change the identity ARN.

They all generate temporary credentials.

Examples:

AWS Identity Chains - more complex

By following the chain backwards, now we know “who did it”!

Next question - “what did they do?”

- We have all ARNs related to the activity
- So, shall we just search for all events with the ARNs?
- ...

ARNs aren't unique; access keys are

Multiple people/services can use “arn:aws:sts::222222222222:assumed-role/admin/itadmin” simultaneously.

Searching for all events with this ARN can lead to results from different “sessions”.

So, what are 100% unique*? API access keys!

Following the access keys

With API calls, easy - just follow the identity chain.

Following the access keys

With API calls, easy - just follow the identity chain.

However, web sessions are... a bit different.

- Web console only requires username and password
- All AWS API calls require API access key + secret key
- So... how does the web console *work*?

Web console internals

- User logs in to web with username and password
- Behind the scenes, temporary API credentials are dynamically generated
- Web console makes API calls on your behalf and displays results
- Different access key generated per region

How to find these API access keys?

Web console internals

- User logs in to web with username and password
- Behind the scenes, temporary credentials are generated
- Web console uses these for making API requests

Browsing the EC2 service page

```
or SwitchRole / RenewRole
"eventName": "ConsoleLogin",
"eventTime": "2021-08-27T19:42:56Z",
"userIdentity": {
  "arn": "arn:aws:iam::111111111111:user/eliav",
  ...
}
```

```
"eventName": "DescribeVolumeStatus",
"eventName": "DescribeAvailabilityZones",
"eventName": "DescribeInstances",
"eventTime": "2021-08-27T19:43:02Z",
"userIdentity": {
  "accessKeyId": "ASIAEXAMPLE01234567",
  "arn": "arn:aws:iam::111111111111:user/eliav",
  "sessionContext": {
    "attributes": {
      "creationDate": "2019-01-21T19:42:56Z",
    },
  },
}
```

Web console internals

- User logs in to web with username and password
- Behind the scenes, temporary credentials are dynamically generated
- Web console uses these for making API calls on your behalf and displays results
- Different access key generated per region

How to find these API access keys?

OK, now we have all relevant access keys for the session!

Now what?

- Now we need to see which actions those access keys did during the session
- We can simply search for all CloudTrail events with these access keys!
- Well... *technically* true, but it's hard to consume:
 - Every single API call is logged separately
 - Simple web sessions often generate thousands of events
 - Logging is *not entirely* comprehensive
 - Varying levels of logging across services

Some CloudTrail quirks... #1

resources field

- Points to “on what was the action done”
- Critical for context
 - e.g. Prod DC vs. dev test machine

Only being populated by ~10%-15% of the services :(

- Non-populating services: IAM, EC2, Lambda, RDS, Secrets Manager, etc...
- We use this field when populated

resources

A list of resources accessed in the event. The field can contain the following information:

- Resource ARNs
- Account ID of the resource owner
- Resource type identifier in the format: `AWS::aws-service-name::data-type-name`

Optional: True

Some CloudTrail quirks... #2

readOnly field

- Indicates if API call changed resources or not
- Helps zooming in on the sensitive/interesting actions
- ~~Isn't always populated :(~~
 - Historically, only ~20% populated
 - During Q4/20, 20% -> 100% population!
- Isn't necessarily a good indicator - these are read-only:
 - STS AssumeRole, GetSessionToken
 - S3 GetObject
 - So, we maintain a list of “sensitive read-only” events

readOnly

Identifies whether this operation is a read-only operation. This can be one of the following values:

- `true` – The operation is read-only (for example, `DescribeTrails`).
- `false` – The operation is write-only (for example, `DeleteTrail`).

Optional: True

Some CloudTrail quirks... #3

requestParameters field - for target resource

- When `resources` unpopulated, we can use `requestParameters`
 - Each API targeting a resource has some request parameter
 - Unfortunately, the parameter names aren't standardized
 - For example, `AttachRolePolicy` receives `policyArn` but `UpdatePolicy` receives `policyId`
 - Also, when API call fails with IAM `AccessDenied`, `requestParameters` is empty :(ul> - However, `errorMessage` is not :)
- Generic parameter - `filterSet:items`
 - (in "resource-searching" API calls)

```
{
  "errorCode": "AccessDenied",
  "eventName": "GetKeyRotationStatus",
  "eventSource": "kms.amazonaws.com",
  "requestParameters": null,
  ...
  "errorMessage": "User: arn:aws:sts::ACCOUNT_ID:assumed-role/ROLE_NAME/ROLE_SESSION_NAME
                   is not authorized to perform: kms:GetKeyRotationStatus on resource:
                   arn:aws:kms:us-east-1:ACCOUNT_ID:key/KEY_ID",
}
```

Some CloudTrail quirks... #3

requestParameters field - for target resource

- When `resources` unpopulated, we can use `requestParameters`
 - Each API targeting a resource has some request parameter
- Unfortunately, the parameter names aren't standardized
 - For example, `AttachRolePolicy` receives `policyArn` but `UpdatePolicy` receives `policyId`
- Also, when API call fails with IAM `AccessDenied`, `requestParameters` is empty :(
 - However, `errorMessage` is not :)
- Generic parameter - `filterSet:items`
 - (in "resource-searching" API calls)

```
{
  {
    "eventName": "DescribeInstances",
    "eventSource": "ec2.amazonaws.com",
    "requestParameters": {
      "filterSet": {"items":
        [{"name": "tag:Name", "valueSet": {"items": [{"value": "web-app-001-prod"}]}}]}
    }
  }
}
```

So, best effort

To summarize all events in a consumable way, we group by API call, and:

- Count number of total calls
- Count successful / failed calls
- Extract a sample resources JSON (if populated)
- Extract target resource from IAM access denied error messages
- Extract a sample requestParameters JSON (for non-read-only events)
- Extract a sample requestParameters filter (for read-only events)
- Extract a sample error message

Moving on - more CloudTrail quirks

Fun quirk #1 - CloudTrail source IP spoofing

When using compromised AWS API credentials, an attacker can spoof the source IP that appears in the victim's CloudTrail logs.

Fun quirk #2 - API access key recycling

- API access keys are supposed to be unique...

Credentials

PDF

AWS credentials for API authentication.

Contents

AccessKeyId

The access key ID that identifies the temporary security credentials.

Type: String

Length Constraints: Minimum length of 16. Maximum length of 128.

Pattern: `[\w]*`

Required: Yes

Expiration

The date on which the current credentials expire.

Type: Timestamp

Understanding Unique ID Prefixes

IAM uses the following prefixes to indicate what type of resource each unique ID applies to.

Prefix	Resource Type
ABIA	AWS STS service bearer token
ACCA	Context-specific credential
AGPA	Group
AIDA	IAM user
AIPA	Amazon EC2 instance profile
AKIA	Access key
ANPA	Managed policy
ANVA	Version in a managed policy
APKA	Public key
AROA	Role
ASCA	Certificate
ASIA	Temporary (AWS STS) keys

Fun quirk #2 - API access key recycling

- API access keys are supposed to be unique...
- Or so I thought
- Turns out they are recycled across identities

Thank you for contacting us. I'll be assisting you with this case today.

From the case notes, I understand that while investigating Cloudtrail logs for your customers, you saw that in some cases the access key IDs assigned after AssumeRole call were same for some users and these access key IDs were valid for overlapping time period. Please correct me if I have misunderstood.

This is undesired behavior and access key IDs are unique identifiers for an IAM entity. As you correctly understood, two entities having the same access key ID can cause logging and investigating issues difficult as Cloudtrail will have all identical fields for both the entities (if role assumed and the RoleSessionName used are also the same). Please note, session token and secret access key are not logged in cloudtrail for security purposes.

Fun quirk #2 - API access key recycling

- API access keys are supposed to be unique...
- Or so I thought
- Turns out they are recycled across identities

Thank you for contacting us. I'll be assisting you with this case today.

From the case
the access key

Please note, s

Thank you for writing back to us.

First of all, I would like to appreciate the amount of research you have done on Cloudtrail logs and access keys - it is very impressive!

I checked all the event IDs you provided and can confirm this behavior (Same access key IDs with both overlapping and non-overlapping time periods).

With this information, I have escalated this issue to our IAM service team. They should be able to clarify this behavior and answer if this is desired behavior or not for both scenarios(with and without overlapping time periods)

Fun quirk #2 - API access key recycling

- API access keys are supposed to be unique...
- Or so I thought
- Turns out they are recycled across identities

Thank you for contacting us. I'll be assisting you with this case today.

I checked a
overlappin

With this ir
answer if tl

Thank you for your continued patience while we were investigating this issue.

I got the following update from the service team:

Is this desired behavior?

>>> This is expected behavior. Due to the sheer amount of AssumeRoll calls made throughout AWS the ASIA**** access key identifier will eventually be generated again(even within same time frame). Remember that in order to make an API call with temporary credentials you will have to supply an access key id, a secret access key, and a session token. Those three combinations are permanently unique. I understand that you cannot search CloudTrail via secret access key or session token, and that if an access key is reused it could cause some confusion in some cases.

Fun quirk #2 - API access key recycling

- API access keys are supposed to be unique...
- Or so I thought
- Turns out they are recycled across identities

Understanding Unique ID Prefixes

IAM uses the following prefixes to indicate what type of resource each unique ID applies to.

Prefix	Resource Type
ABIA	AWS STS service bearer token
ACCA	Context-specific credential
AGPA	Group
AIDA	IAM user
AIPA	Amazon EC2 instance profile
AKIA	Access key
ANPA	Managed policy
ANVA	Version in a managed policy
APKA	Public key
AROA	Role
ASCA	Certificate
ASIA	Temporary (AWS STS) keys

Understanding unique ID prefixes

IAM uses the following prefixes to indicate what type of resource each unique ID applies to.

Prefix	Resource type
ABIA	AWS STS service bearer token
ACCA	Context-specific credential
AGPA	User group
AIDA	IAM user
AIPA	Amazon EC2 instance profile
AKIA	Access key
ANPA	Managed policy
ANVA	Version in a managed policy
APKA	Public key
AROA	Role
ASCA	Certificate
ASIA	Temporary (AWS STS) access key IDs use this prefix but are unique only in combination with the secret access key and the session token.

Fun quirk #2 - API access key recycling

- API access keys are supposed to be unique...
- Or so I thought
- Turns out they are recycled across identities
- Not a security risk
 - Happens only rarely
 - Only recycled in-account
 - No “cross-permissions” possible

What AWS can improve

- More comprehensive logging
- Better documentation
- Improve AWS detective

Thank you
